# CONVEX ANALYSIS WORKSHOP

### RYUTO SAITO

### 1. Convex functions

I made this material referring to [1].

## 1.1. Definitions.

**Definition 1.1.1** (Convex function): A function  $f: \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$  is *convex* if **dom** f is a convex set and

$$\forall \boldsymbol{x}, \boldsymbol{y} \in \operatorname{\mathbf{dom}} f, \forall t \in [0, 1], f(t\boldsymbol{x} + (1 - t)\boldsymbol{y}) \le tf(\boldsymbol{x}) + (1 - t)f(\boldsymbol{y}) \quad (1)$$

where  $\operatorname{dom} f$  is the effective domain of f:

$$\operatorname{dom} f := \{ \boldsymbol{x} \mid f(\boldsymbol{x}) < \infty \}. \tag{2}$$

**Definition 1.1.2** (Concave function): A function f is said to be *concave* if -f is convex.

**Definition 1.1.3** (Non-decreasing and non-increasing): A function  $f: \mathbb{R} \to \mathbb{R}$  is called *non-decreasing* if

$$\forall a, b \in \mathbb{R}, a \le b \Longrightarrow f(a) \le f(b). \tag{3}$$

Likewise, a function  $f: \mathbb{R} \to \mathbb{R}$  is called *non-increasing* if

$$\forall a, b \in \mathbb{R}, a \le b \Longrightarrow f(a) \ge f(b). \tag{4}$$

## 1.2. Exercise.

**Proposition 1.2.1** (Scalar composition): For  $h : \mathbb{R} \to \mathbb{R} \cup \{\infty\}$ ,  $g : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ , define  $f : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$  by

$$f(\boldsymbol{x}) \coloneqq h(g(\boldsymbol{x})) \tag{5}$$

with

$$\operatorname{dom} f = \{ \boldsymbol{x} \in \operatorname{dom} g \mid g(\boldsymbol{x}) \in \operatorname{dom} h \}. \tag{6}$$

Then f is convex if

- h is convex and nondecreasing and q is convex, or
- h is convex and nonincreasing and g is concave.

*Proof*: First, we prove that f is convex if h is convex and nondecreasing and g is convex.

Let  $x, y \in \text{dom } f$ , and  $t \in [0, 1]$ . Since  $x, y \in \text{dom } f$ , we have  $x, y \in \text{dom } g$ 

and  $g(\boldsymbol{x}), g(\boldsymbol{y}) \in \operatorname{dom} h$ . From the convexity of  $\operatorname{dom} g$ ,  $t\boldsymbol{x} + (1-t)\boldsymbol{y} \in \operatorname{dom} g$ . Then, since g is convex, we have

$$g(t\boldsymbol{x} + (1-t)\boldsymbol{y}) \le tg(\boldsymbol{x}) + (1-t)g(\boldsymbol{y}). \tag{7}$$

Since  $g(\mathbf{x}), g(\mathbf{y}) \in \mathbf{dom} h$  and  $\mathbf{dom} h$  is convex, we have  $tg(\mathbf{x}) + (1 - t)g(\mathbf{y}) \in \mathbf{dom} h$ . Then,

$$h(tg(\boldsymbol{x}) + (1-t)g(\boldsymbol{y})) < \infty. \tag{8}$$

Using the assumption that h is nondecreasing and (7), it follows that

$$h(g(t\boldsymbol{x} + (1-t)\boldsymbol{y})) \le h(tg(\boldsymbol{x}) + (1-t)g(\boldsymbol{y})). \tag{9}$$

From (8) and (9), we get

$$h(g(t\boldsymbol{x} + (1-t)\boldsymbol{y})) < \infty, \tag{10}$$

which means  $g(t\boldsymbol{x}+(1-t)\boldsymbol{y})\in\operatorname{dom} h$ . Since  $t\boldsymbol{x}+(1-t)\boldsymbol{y}\in\operatorname{dom} g$  and  $g(t\boldsymbol{x}+(1-t)\boldsymbol{y})\in\operatorname{dom} h$ , we get  $t\boldsymbol{x}+(1-t)\boldsymbol{y}\in\operatorname{dom} f$ . Therefore,  $\operatorname{dom} f$  is convex set. From the convexity of h, we have

$$h(tg(\boldsymbol{x}) + (1-t)g(\boldsymbol{y})) \le th(g(\boldsymbol{x})) + (1-t)h(g(\boldsymbol{y})). \tag{11}$$

From (9) and (11), we get

$$h(g(tx + (1-t)y)) \le th(g(x)) + (1-t)h(g(y)).$$
 (12)

That is

$$f(t\boldsymbol{x} + (1-t)\boldsymbol{y}) \le tf(\boldsymbol{x}) + (1-t)f(\boldsymbol{y}). \tag{13}$$

Then, we have shown that f is convex if h is convex and nondecreasing and q is convex.

Next, we prove that f is convex if h is convex and nonincreasing and g is concave. Let  $\mathbf{x}, \mathbf{y} \in \operatorname{dom} f$ ,  $t \in [0,1]$  and  $g : \mathbb{R}^n \to \mathbb{R}$ . Since  $\mathbf{x}, \mathbf{y} \in \operatorname{dom} f$ , we have  $\mathbf{x}, \mathbf{y} \in \operatorname{dom} g$  and  $g(\mathbf{x}), g(\mathbf{y}) \in \operatorname{dom} h$ . Recall that  $g(\mathbf{x}), g(\mathbf{y}), g(t\mathbf{x} + (1-t)\mathbf{y}) \in \mathbb{R}$ , we have  $-g(\mathbf{x}) < \infty$ ,  $-g(\mathbf{y}) < \infty$  and  $g(t\mathbf{x} + (1-t)\mathbf{y}) < \infty$ . That is  $\mathbf{x}, \mathbf{y} \in \operatorname{dom} -g$  and  $t\mathbf{x} + (1-t)\mathbf{y} \in \operatorname{dom} g$ . Since  $t\mathbf{x} + (1-t)\mathbf{y} \in \operatorname{dom} g$ ,  $\operatorname{dom} g$  is convex. From the convexity of  $\operatorname{dom} -g$ ,  $t\mathbf{x} + (1-t)\mathbf{y} \in \operatorname{dom} -g$ . Then, since -g is convex, we have

$$-g(tx + (1-t)y) \le t(-g(x)) + (1-t)(-g(y)).$$
(14)

Multiplying this inequality by -1 yields

$$g(t\boldsymbol{x} + (1-t)\boldsymbol{y}) \ge tg(\boldsymbol{x}) + (1-t)g(\boldsymbol{y}). \tag{15}$$

Since  $g(\mathbf{x}), g(\mathbf{y}) \in \operatorname{dom} h$  and  $\operatorname{dom} h$  is convex, we have  $tg(\mathbf{x}) + (1 - t)g(\mathbf{y}) \in \operatorname{dom} h$ . Then,

$$h(tg(\boldsymbol{x}) + (1-t)g(\boldsymbol{y})) < \infty. \tag{16}$$

Using the assumption that h is nonincreasing and (15), it follows that

$$h(g(t\boldsymbol{x} + (1-t)\boldsymbol{y})) \le h(tg(\boldsymbol{x}) + (1-t)g(\boldsymbol{y})). \tag{17}$$

From (16) and (17), we get

$$h(g(t\boldsymbol{x} + (1-t)\boldsymbol{y})) < \infty, \tag{18}$$

which means  $g(t\boldsymbol{x}+(1-t)\boldsymbol{y})\in\operatorname{dom}h$ . Since  $t\boldsymbol{x}+(1-t)\boldsymbol{y}\in\operatorname{dom}g$  and  $g(t\boldsymbol{x}+(1-t)\boldsymbol{y})\in\operatorname{dom}h$ , we get  $t\boldsymbol{x}+(1-t)\boldsymbol{y}\in\operatorname{dom}f$ . Therefore,  $\operatorname{dom}f$  is convex set. From the convexity of h, we have

$$h(tg(x) + (1-t)g(y)) \le th(g(x)) + (1-t)h(g(y)).$$
 (19)

From (17) and (19), we get

$$h(g(tx + (1-t)y)) \le th(g(x)) + (1-t)h(g(y)).$$
 (20)

That is

$$f(tx + (1-t)y) \le tf(x) + (1-t)f(y).$$
 (21)

Then, we have shown that f is convex if h is convex and nonincreasing and g is concave.
